

Does institutional proliferation undermine cooperation?

Theory and evidence from climate change

A Global climate governance dataset

The global climate dataset is designed as a complement to existing work on international and transnational climate governance research. International climate research has tended to focus on the the United Nations-led climate governance process (see Gupta (2014), Bodansky et al. (2017), and Kaya and Schofield (2020) for examples). A recent boom of transnational climate research focuses on the contributions of public and private non-state actors to governing climate change outside the UN climate process (see Bulkeley et al. (2014), Andonova et al. (2017), and Hale (2020) for examples). However, the literature has largely overlooked the activity of *states* in seeking alternative institutional forums for climate governance. To the extent that the literature has engaged with this activity, it has mostly been to highlight how these institutions pale in comparison to idealized climate mitigation “clubs” (Falkner 2016). As a result, we have little systematic understanding of what these institutions are, why they were established, and why states join them. With global governance as a whole increasingly characterized by institutional density, global climate governance offers insights into how dense institutional environments work.

I create a new dataset to study state participation in institutionalized climate cooperation. My dataset tracks climate governance institutions established since 1990 that include states as members. Like international institutions in general, these institutions vary along a number of design dimensions, such as the number of members, the types of members, their legal obligations, and their independence. However, they are all united in their focus on climate change and their inclusion of national governments as members. In contrast to other datasets that select institutions based on certain design features (see e.g., Pevehouse et al. (2004)), these institutions are selected based on their subject matter and types of members.

I track state membership in institutions over time using publicly available documents on institutions’ websites. No central depository of all international institutions exists. To identify climate institutions, I rely on existing studies, online databases from the UNFCCC, as well as snowballing from the institutions uncovered. Many of these institutions were identified through the secondary literature on transnational climate governance (Bulkeley et al. 2014), international climate governance (Widerberg and Pattberg 2015), and the United Nations Climate Secretariat’s own listings (UN Climate Change 2013). I am confident that this has allowed me to capture close to the full population of climate institutions up to the adoption of the Paris Agreement. The data

Umbrella Group, or cross-cutting diplomatic groups, such as the G77, are not included in my study. In a sense, these negotiating groups constitute the background against which we can evaluate other patterns of organization in climate governance. The Association of Small Island States (AOSIS), by contrast, predates the UNFCCC negotiations and meets regularly outside the COP process, as well as constituting a negotiating group in the COPs. As such, I include AOSIS as a climate governance institution in my dataset.

Third, state membership in the institutions in my dataset must result from governmental decisions to join that particular institution. To join the Climate and Clean Air Coalition, a high-ranking government official needs to submit a statement affirming the organization's principles. In contrast, membership in the Intergovernmental Panel on Climate Change (IPCC) is automatic for state parties to the World Meteorological Organization or the United Nations. Only in the former instance is membership in the institution a choice, and therefore institutions like the IPCC are not included in my dataset.

A related case is when an existing institution develops new climate competencies or when it mainstreams climate considerations into its existing operations. Such institutions are not in the dataset by virtue of this alone because I am interested in how states *choose* to participate in climate governance rather than instances where climate governance is passed on to them. For example, in the early 2000s, the Organization for Economic Cooperation and Development (OECD) created the Climate Change Expert Group (CCXG) as an internal forum on the technical issues in climate change. All OECD members are members of the CCXG by virtue of their membership in the OECD, and so the CCXG is not in the dataset. Similarly, the G20 is not in the dataset, even though the G20 member states adopted rules in 2007 on phasing out fossil fuel subsidies. The OECD and the G20 have developed new competencies in climate change, but they are not stand-alone, purpose-built forums designed to address climate change. By contrast, several international organizations have created new climate institutions where the new institution's membership differs from its parent's. In 2009, the International Energy Agency (IEA) led the creation of the Clean Energy Ministerial (CEM) and only a subset of IEA members are members of CEM. In this case, I treat CEM membership as a choice for IEA members and included the CEM in my study as an instance of states seeking new institutional forums to address climate change.

Finally, the initiatives in question must explicitly pursue governance objectives in relation to

climate change. International rule-making may take the form of public international law, such as treaty law, where parties accept binding international legal obligations (Abbott and Snidal 1998). States or transnational actors may also draft soft law or regulatory standards to meet cooperative goals by weakening any of the precision, bindingness or delegation of hard treaty law (Abbott and Snidal 2000). However, international governance may also take the form of direct operational or financial support for actors and projects, or sharing information or networking different important key actors (Abbott and Snidal 2009). Since many of the initiatives in my study are not treaty-based international organizations, they lack access to hard international law as a way of regulating targets, and must therefore rely on softer forms of governance to steer targets towards goals (Abbott et al. 2015). The governance criteria is more discriminating in the context of TCG, where scholars are interested in separating governance activities from lobbying (Hale and Roger 2014). Defining hard law as a criteria for inclusion would exclude the majority of climate institutions and truncate the dataset in a somewhat arbitrary way. Furthermore, the inclusion of softer initiatives helps re-orient the literature on regime complexity and institutional proliferation away from a narrow focus on rule conflicts and compliance, and toward a broader focus on membership and how states use dense institutional environments.

Figure S-1 demonstrates how these different types of institutional responses to climate change fit together. The UN climate bodies lie at the core of the global response to climate change. These comprise the major UN treaties and other institutions established by or through the UN climate secretariat. Some of these institutions meet the criteria for inclusion in my dataset, such as the Joint Implementation program, where states proactively join and choose to participate in the program—a subset of UNFCCC members choose to manage a portion of their emissions mitigation obligations through the Joint Implementation program, but others decide not to use the program. I include these institutions in my study since they also reflect active state choices to participate in climate governance. However, a number of other UN-emanating institutions do not meet my criteria, as they lack states as members (e.g., the UN Principles for Responsible Investment) or membership is a function of other preexisting institutional memberships (e.g., the IPCC). Since many of the climate institutions emanating from the UN-led process have narrow membership compared to the UNFCCC, I consider their dynamics as comparable, though I do not assume they are identical, to the dynamics of membership in the wider climate environment. The partially overlapping circles in

Figure S-1: Varieties of institutions in climate governance

figure S-1 indicate this relationship.

International institutions in areas outside of climate change have increasingly adopted internal rules about sustainability and climate change. This includes the International Maritime Organization’s attempts to adopt GHG reduction targets for maritime shipping, which have been under consideration since the late 1990s. Similarly, proposals to enforce rules on climate change by linking climate with the trade regime represent the area of possible overlap between UNFCCC rules and those in other issue-areas. The existence of institutions with overlapping functional scope is often referred to as a regime complex. However, the case of climate governance indicates that this concept is under-specified in practice. There may be a large number of institutions within an issue-area (i.e., high intra–issue-area density) and there may be overlap across issue-areas (e.g., trade and climate), but these are actually two concepts that do not need to move in lock-step. It is possible to have a high degree of overlap across issue-areas with only one institution in each issue-area. It is similarly possible to have high intra–issue-area density but little overlap with other

issue-areas. Climate governance blurs a bit of both. There is a high level of intra–issue-area density and some intersection with other issue-areas, such as the new rules on hydrofluorocarbons in the Kigali Amendment to the Montreal Protocol, though most climate linkages remain speculative. In this study, I treat within climate institutional density only. I consider these institutions as tied together by common reference points. Granted, the ultimate success or failure of international rules on carbon emissions may require some issue-linkage, but it is not important for the research questions in this study to examine every possible issue-linkage.

conduct two empirical tests to demonstrate how this inclusion criteria has a very minor effect on the relationships I explore in the paper. First, I exclude AOSIS from the climate institutions dataset, re-run the IRT model to estimate ideal points, and then regress ambition on these alternative ideal points. I find the same relationship. Second, I include all the other UN negotiating groups in the IRT model and regress ambition on these alternative ideal points, and again find the same relationship. I present the correlation across ideal points for these alternative samples of institutions in table S-4 and the regression results in table S-5.
